eeg calculations worksheet pdf: Normative Developmental Equations for the EEG and Their Sensitivity to Neurological and Psychiatric Disorders E. R. John, L. S. Prichep, Nathan S. Kline, NEW YORK UNIV MEDICAL CENTER NY., 1988 Although the electroencephalogram (EEG) is altered by many brain dysfunctions, its clinical utility has been severely limited by reliance upon visual pattern recognition and subjective interpretation. Not only is the concordance poor between electroencephalographers and the test-retest reliability low, but many changes due to more subtle dysfunctions are simply not apparent by visual inspection. Accordingly, there has been increasing interest in developing methods for objective computer extraction of quantitative features with diagnostic utility from brain electrical activity. Our laboratories have been engaged in this endeavor since 1973. Our goal has been not only to replace subjective judgements by objective quantification, but to extend the utility of electrophysiological examinations beyond their traditional role in the detection of neurological disorders to the assessment of cognitive impairments and the evaluation of psychiatric patients. In many disorders, similar behavioral symptoms may be displayed for quite different underlying patients. In many disorders, similar behavioral symptoms may be displayed for quite different underlying reasons. For example, learning disabilities may be due to motivational or psychosocial factors, or to sensory deficits or brain dysfunctions. An elderly person may display problems with recent memory because of a sense of lack of purpose or because of organic changes caused by Alzheimer's disease or multiple infarcts. Depression may be a reaction to the disintegration of personal relationships or reflect imbalance in neurotransmitters. (js).

Furthermore, we study the dynamical evolution of the probability density function (PDF) of the detrended EEG signals by nonextensive statistical modeling. It displays a scale-independent property, which is markedly different from the usual scale-dependent PDF evolution and cannot be described by the Fokker-Planck equation.

eeg calculations worksheet pdf: Combining EEG Source Dynamics Results Across Subjects, Studies and Cognitive Events Nima Bigdely-Shamlo, 2014 This dissertation contains several projects, each providing a solution contributing to an aspect of group-level source-level EEG analysis. I explore different methods to extract better EEG measures from individual subjects: regression to reduce confounds originated from temporal proximity of cognitive events, optimal low-pass filtering to calculate better ERPs and collaborative averaging to obtain better measures from small numbers of trials. I introduce two methods for combining source-based EEG information, calculated with ICA and equivalent dipole localization, across subjects in a study: Measure Projection Analysis (MPA) allows study-level analysis for measures, such as ERP and ERSP, that are associated with single brain areas while Network Projection Analysis enables combining network measures, such as effective connectivity, associated with an ordered pair of brain area. The last two chapters of the dissertation are dedicated to discussing meta-analysis, i.e. combining information across multiple studies. This is a subject that is well developed in the fMRI field but is new in the field of source-based EEG analysis. I introduce a user-friendly schema (Hierarchical Event

Descriptors, or HED), based on established cognitive ontologies, to describe cognitive event and states in a hierarchical and machine readable manner. HED facilitates automated meta-analysis and can benefit researchers by simplifying statistical designs and streamlining event information handling. The current EEG analysis-publication workflow mostly documents qualitative descriptions of event-related EEG dynamics. This makes it difficult to look for comparable results in the literature since search options are limited to textual descriptions and/or similar-appearing results depicted in the paper figures. In the final chapter I demonstrate a method for quantitative comparison of source-resolved results (e.g., ERPs, ERSPs) across different EEG studies. The proposed source-resolved EEG measure search engine receives search queries composed of event-related EEG measures, each associated with an estimated brain source location to be compared using Measure Projection Analysis (MPA) to all records in the search engine database accumulated by automated data analysis workflows applied to data of multiple studies. A similarity-ranked list of events from other studies that have elicited similar EEG dynamics in nearby source-locations is then returned to the user along with their experiment and event metadata.

eeg calculations worksheet pdf: *EEG and MEG forward modelling* Sylvain Vallaghé, 2008 Le travail présenté dans cette thèse s'inscrit dans l'étape de modélisation du problème direct en électroencéphalographie (EEG) et magnétoencéphalographie (MEG). La première partie traite du calcul des solutions du problème direct, gouvernées par des équations aux dérivées partielles. Nous présentons tout d'abord une nouvelle méthode éléments finis (FEM) basée sur des maillages cubiques réguliers et une description implicite du domaine qui permet de résoudre à faible coût le problème direct pour des géométries réalistes. Nous associons à cette méthode des équations réciproques générales, obtenues par la méthode de l'adjoint, qui permettent de calculer efficacement les lead fields de tout type de capteur EEG ou MEG. La deuxième partie concerne le choix des conductivités électriques dans les modèles directs en EEG. Dans un premier temps, nous effectuons une analyse de sensibilité globale des topographies EEG aux conductivités pour des modèles de tête classiques à trois ou quatre couches. S'appuyant sur les résultats de cette analyse, nous proposons ensuite une méthode de calibration des conductivités basée sur l'utilisation de potentiels évoqués somesthésiques.
