Key Milestones in Plant Evolution

Understanding the major events in plant evolution is crucial for grasping the overall narrative of how plants came to dominate terrestrial ecosystems.

1. The Origin of Photosynthetic Life

The story begins over 3.5 billion years ago with simple photosynthetic microorganisms like cyanobacteria. These ancestors began producing oxygen as a byproduct of photosynthesis, gradually transforming Earth's atmosphere.

2. The Rise of Algae

Approximately 1 billion years ago, complex multicellular algae evolved. These aquatic plants laid the groundwork for future terrestrial plants.

3. Transition to Land: The First Land Plants

Around 470 million years ago, the earliest land plants appeared. These were non-vascular plants like mosses and liverworts, which lacked specialized tissues for water and nutrient transport.

4. Vascular Plants and the Development of Conductive Tissues

By about 420 million years ago, vascular plants such as ferns and horsetails evolved. They developed xylem

and phloem, enabling them to grow taller and transport water and nutrients efficiently.

5. The Evolution of Seed Plants

Approximately 360 million years ago, seed-producing plants, including gymnosperms like conifers, emerged. Seeds protected embryonic plants and allowed for dispersal over greater distances.

6. The Rise of Flowering Plants (Angiosperms)

Around 140 million years ago, angiosperms evolved, introducing flowers and fruit. They rapidly diversified and became the dominant plant group today.

Exploring Plant Evolution Through the Webquest

A plant evolution webquest typically involves various activities designed to deepen understanding of evolutionary concepts.

Briggs considers the implications of these for our understanding of the evolution of flowering plants, as well as the potential for future advances. Numerous new sections on important topics such as the evolutionary impact of human activities, taxonomic challenges, gene flow and distribution, hybridisation, speciation and extinction, conservation and the molecular genetic basis of breeding systems will ensure that this remains a classic text for both undergraduate and graduate students in the field.

plant evolution webquest: *Plant Evolution and the Origin of Crop Species* Ravikiran Vasant Mane, 2016 Evolution is the force that shapes our living world. Countless different kinds of plants and animals pack the earth and each species is itself composed of a wide range of morphologies and adaptations. These species are continually being modified as they face the realities of their particular environments. In its simplest sense, evolution can be defined as a change in gene frequency over time. Genetic variability is produced by mutation and then that variability is shuffled and sorted by the various evolutionary forces. It does not matter whether the species are cultivated or wild, the basic evolutionary processes are the same.
