osteitis pubis exercises pdf: THE POSTPARTUM PRESENTATION OF OSTEITIS PUBIS: A CASE REPORT. , 2017 Introduction: Osteitis pubis is characterised by painful and inflammatory condition of pubic symphysis. Even though, this pathology is usually associated with overuse injuries, pelvic surgery and trauma; it can be rarely seen in postpartum period. Purpose: In this study we aimed to report a postpartum case of osteitis pubis who had admitted to our department with hip pain. Method: A 28-year-old patient was referred to our hospital with bilateral mechanical hip pain. Her medical history revealed that she was in postpartum period and her pain had increased gradually after the parturition. On physical examination bilateral hip joint movements were painful. The strength of the right hip muscles were 3+/5 and the left hip muscles were 4/5. Results: Routine laboratory tests revealed that the serum concentration of C reactive protein (CRP) was 6.7 mg/dl and the erythrocyte sedimentation rate was 36 mm/h. A magnetic resonance imaging (MRI) was also planned for the patient. MRI findings showed subcortical and medullary bone marrow edema in the pubic bones bilaterally which were compatible with osteitis pubis. The patient has also referred to the department of gynecology. The gynecology department had detected a vaginal infection and applied drug therapy to the patient. The conservative treatment included exercise programme was planned to the patient by our department. After the exercise programme VAS pain score was decreased from 100 mm to 60 mm. Discussion and Conclusion: Osteitis pubis occurred in postpartum period is a rare clinical disorder. Clinicians should be aware of this clinical entity, especially in patients after the parturition. The diagnosis should be confirmed by clinical, laboratory and radiological examinations.
