Understanding Codominance

What Is Codominance?

Codominance occurs when two alleles at a gene locus are both fully expressed in a heterozygous individual. Unlike dominant-recessive inheritance, where one allele masks the presence of another, codominance results in a phenotype that displays both traits simultaneously.

Key Features of Codominance

- Both alleles are expressed equally in heterozygotes.
- The phenotype shows a combination or both traits clearly visible.
- Common examples include blood group alleles (AB blood type) and certain animal coat patterns.

Examples of Codominance

1. **Blood Types:** Blood group AB results from the codominance of A and B alleles.

2. **Animal Coat Color:** Roan cattle display a mixture of white and red hairs, both expressed simultaneously.

Genotypic and Phenotypic Ratios in Codominance

- When crossing two heterozygotes (e.g., AB x AB), the genotypic ratio is 1:2:1.
- The phenotypic ratio typically is 1:2:1, representing the three possible blood types: A, B, and AB, depending on the alleles inherited.

Understanding Incomplete Dominance

What Is Incomplete Dominance?

Incomplete dominance is a form of inheritance where the heterozygous phenotype is intermediate between the two homozygous phenotypes. This results in a blending effect, where neither allele is completely dominant over the other.

Key Features of Incomplete Dominance

- The heterozygote exhibits a phenotype that is a blend of both homozygous traits.
- It demonstrates partial dominance rather than complete dominance.
- Common in traits such as flower color, skin pigmentation, and other morphological features.

Examples of Incomplete Dominance

1. **Flower Color:** For instance, crossing red-flowered (RR) and white-flowered (rr) plants produces pink (Rr) offspring.
2. **Human Skin Pigmentation:** Intermediary melanin levels can result in skin tones that are between the two parental phenotypes.

Genotypic and Phenotypic Ratios in Incomplete Dominance

- Crossing two heterozygotes ($Rr \times Rr$) yields a genotypic ratio of 1:2:1.
- The phenotypic ratio is typically 1:2:1, representing the three observable traits: red, pink, and white in flower color examples.

Sample Worksheet Questions and Answer Key

Question 1: Define codominance and give an example.

Answer: Codominance is a genetic phenomenon where both alleles at a locus are fully expressed in a heterozygous individual, resulting in a phenotype that shows both traits simultaneously. An example is the AB blood type, where the A and B alleles are both expressed.

Question 2: Describe the difference between incomplete dominance and codominance.

Answer: Incomplete dominance results in a blended phenotype that is intermediate between the two homozygous traits (e.g., pink flowers from red and white parents). In contrast, codominance involves the simultaneous expression of both alleles without blending, producing a phenotype that exhibits both traits distinctly (e.g., AB blood type).

Question 3: In a certain flower species, red (R) and white (W) alleles show incomplete dominance. What will be the color of the heterozygous offspring (RW)?

Answer: The heterozygous offspring (RW) will have pink flowers, which is an intermediate phenotype resulting from incomplete dominance.

Question 4: Cross a heterozygous red flower (RR) with a white flower (rr). What are the possible genotypes and phenotypes of the offspring?

Answer: The possible genotypes are Rr, and all will have red flowers since R is dominant over r. The genotypic ratio is 1 Rr : 0 RR : 0 rr;

phenotypically, 100% will have red flowers.

Question 5: If two heterozygous individuals (Rr) for flower color are crossed, what are the genotypic and phenotypic ratios?

Answer:

- Genotypic ratio: 1 RR : 2 Rr : 1 rr
- Phenotypic ratio: 1 red : 2 pink : 1 white (assuming incomplete dominance)

Question 6: Explain why blood type AB demonstrates codominance.

Answer: Blood type AB exhibits codominance because both the A and B alleles are expressed equally and distinctly on the surface of red blood cells, resulting in a phenotype that displays both antigen types simultaneously without blending.

Question 7: How does the inheritance pattern of incomplete dominance affect the phenotype in a heterozygous individual?

Answer: In incomplete dominance, the heterozygous individual has a phenotype that is intermediate between the two homozygous parents, often appearing as a blend or a new trait, rather than expressing either trait fully.

Question 8: Why is understanding the difference between codominance and incomplete dominance important in genetics?

Answer: Recognizing the difference helps in predicting inheritance patterns, understanding how traits are expressed, and accurately interpreting genetic crosses. It also aids in understanding the genetic basis of various human and animal traits, as well as in medical genetics and breeding programs.

Understanding Codominance and Incomplete Dominance

Before exploring worksheet specifics, it's crucial to establish a clear understanding of these two inheritance patterns.

What is Codominance?

Codominance occurs when two alleles at a specific gene locus are equally expressed in the phenotype, resulting in offspring that display both traits simultaneously without blending. Unlike complete dominance, where one allele masks the effect of the other, codominance ensures that both traits are distinctly visible.

Real-world example:

- AB blood type in humans

The A and B alleles are codominant. Individuals with genotype AB exhibit blood that has both A and B antigens on their red blood cells, showcasing both traits side by side.

Key features of codominance:

- Both alleles contribute equally to the phenotype
- No blending occurs; traits are expressed distinctly
- Often observed in blood types, coat colors in animals, and plant pigmentation

What is Incomplete Dominance?

Incomplete dominance describes a scenario where neither allele is completely dominant over the other, leading to a blended or intermediate phenotype in heterozygous individuals.

Real-world example:

- Snapdragon flower color

Crossing red-flowered (RR) and white-flowered (WW) plants results in pink (RW) offspring, displaying an intermediate trait.

Key features of incomplete dominance:

- Phenotype of heterozygotes is a blend of the two parental traits
- The dominant and recessive alleles are not fully expressed separately
- Common in traits like flower color, coat color, and certain genetic disorders
