Post-simulation, students should analyze their data to draw conclusions about energy conservation and the impact of different factors. Discussion questions can facilitate understanding and clarify misconceptions.

Key Concepts Covered in the Phet Energy Skate Park Worksheet

Potential Energy (PE)

Potential energy is stored energy based on an object's position or configuration. In the skate park simulation, it is highest at the top of the track and depends on:

- Height above the ground
- Mass of the skateboarder

Kinetic Energy (KE)

Kinetic energy is the energy of motion. It increases as the skateboarder speeds up, especially at the bottom of the track. It is calculated using:

- $KE = \frac{1}{2} mv^2$

where m is mass and v is velocity.

Conservation of Energy

One of the core principles explored is the conservation of mechanical energy, which states that in the absence of friction, total energy remains constant:

- Total Energy = PE + KE

Students learn to observe how potential energy decreases as kinetic energy increases, and vice versa, during motion.

Effects of Friction and Non-Conservative Forces

Frictional forces convert some mechanical energy into thermal energy, causing a decrease in total mechanical energy. The worksheet prompts students to consider these effects and understand that real-world systems often deviate from ideal energy conservation.

Common Challenges and Tips for Success

Understanding Energy Transformations

- Focus on specific points along the track to observe energy changes
- Use diagrams or sketches to visualize energy shifts

Dealing with Friction and Other Forces

- Recognize that friction causes energy loss, making total energy less than initial values
- Adjust the simulation to reduce friction for idealized observations

Data Accuracy and Analysis

- Record multiple measurements to ensure reliability
- Compare theoretical calculations with simulation data for validation
