Review Sheet 11: Articulations and Body Movements

Review sheet 11 articulations and body movements is an essential component of anatomy and physiology education, offering a detailed overview of how the human skeletal system facilitates movement through joints and various body motions. Understanding these concepts is fundamental for students, healthcare professionals, and anyone interested in human biology, sports science, physical therapy, or fitness. This review sheet covers the types of articulations (joints), their structural classifications, functional classifications, and the range of movements they enable, providing a comprehensive guide to human body mechanics.

Understanding Human Articulations (Joints)

Articulations, commonly known as joints, are points where two or more bones meet. They are crucial for providing mobility and stability to the skeletal system. Joints are classified based on their structure and function, influencing the types of movements they permit.

Structural Classification of Joints

Structural classifications categorize joints based on the material binding the bones and the presence of a joint cavity. The main types include:

- 1. Fibrous Joints**
- 2. Cartilaginous Joints**
- 3. Synovial Joints**

Functional Classification of Joints

Functional classification describes the degree of movement allowed at the joint:

1. **Synarthrosis** – immovable joints
2. **Amphiarthrosis** – slightly movable joints
3. **Diarthrosis** – freely movable joints

Structural Types of Joints and Their Characteristics

Fibrous Joints

Fibrous joints are connected by dense fibrous connective tissue and are mostly immovable. Examples include:

- sutures of the skull
- syndesmoses (interosseous membranes between long bones)

Cartilaginous Joints

Cartilaginous joints are connected entirely by cartilage and allow limited movement. Examples include:

- synchondroses (epiphyseal plates)
- symphyses (pubic symphysis, intervertebral discs)

Synovial Joints

Synovial joints are characterized by a fluid-filled joint cavity, allowing a wide range of movement. They are the most common and most mobile joints in the body. Key features include:

- articular cartilage
- synovial membrane
- joint capsule
- synovial fluid

Types of Synovial Joints and Examples

Plane (Gliding) Joints

Allow sliding or gliding movements. Examples include:

- interphalangeal joints

Pivot Joints

Allow rotational movement around a single axis. Examples include:

- proximal radioulnar joint
- atlantoaxial joint (neck rotation)

Condylloid (Ellipsoidal) Joints

Permit movement in two planes, including flexion, extension, abduction, and adduction. Examples include:

- wrist joint

Articulations and Body Movements: A Comprehensive Review of Review Sheet 11

Understanding the intricacies of articulations (joints) and body movements is fundamental to comprehending human biomechanics, kinesiology, and movement sciences. This review delves deeply into the classification, structure, function, and types of articulations, as well as the mechanics and classifications of body movements. This detailed analysis aims to provide a thorough grasp of how our skeletal system facilitates movement and stability.

Introduction to Articulations and Body Movements

The human body is an astonishingly complex system where bones, muscles, ligaments, and tendons work synergistically to produce movement and maintain stability. Articulations serve as the junctions where bones meet, enabling mobility, while body movements describe the specific actions performed by muscles acting across these joints.

Understanding these elements is essential for multiple disciplines, including medicine, sports science, physical therapy, and anatomy education. The two core components—articulations and movements—are interconnected; joints provide the mechanical foundation for movement, which is executed through muscle contractions.

Classification of Articulations (Joints)

Articulations are classified based on their structure and function. Recognizing the different types of joints helps elucidate their roles in facilitating movement and providing stability.

Structural Classification of Joints

Joints are categorized into three main types based on the material uniting the bones and the presence of a joint cavity:

1. Fibrous Joints (Synarthroses)
 - Bones are connected by dense fibrous connective tissue.
 - Generally immovable or permit very limited movement.
 - Examples:
 - Sutures of the skull
 - Syndesmoses (e.g., distal tibiofibular joint)
 - Gomphoses (e.g., tooth sockets)
2. Cartilaginous Joints (Amphiarthroses)
 - Bones are united by cartilage.
 - Allow slight movement, providing strength and flexibility.
 - Examples:
 - Symphyses (e.g., pubic symphysis, intervertebral discs)
 - Synchondroses (e.g., epiphyseal plates, costal cartilages)
3. Synovial Joints (Diarthroses)
 - Characterized by a joint cavity filled with synovial fluid.

- Freely movable joints, crucial for most limb movements.
- Examples:
- Knee, elbow, shoulder, hip, wrist, ankle

Functional Classification of Joints

Based on the degree of movement permitted, joints are classified as:

1. Synarthrosis (Immovable Joints)
 - No movement; tightly connected.
 - Examples: sutures of the skull.
2. Amphiarthrosis (Slightly Movable Joints)
 - Limited movement; provides strength and flexibility.
 - Examples: intervertebral discs.
3. Diarthrosis (Freely Movable Joints)
 - Wide range of movement; most common in limbs.
 - Examples: shoulder joint, knee joint.

Structural Types of Synovial Joints

Synovial joints are the most mobile joints in the human body. Their structure is designed to facilitate movement while maintaining stability.

Types of Synovial Joints

1. Plane (Gliding) Joints
 - Flat or slightly curved surfaces; allow sliding movements.
 - Examples: intercarpal, intertarsal joints.
2. Hinge Joints
 - Permit movement primarily in one plane (uniaxial).
 - Examples: elbow, interphalangeal joints.
3. Pivot Joints
 - Allow rotation around a single axis.
 - Examples: atlantoaxial joint (C1-C2), proximal radioulnar joint.
4. Condylloid (Ellipsoidal) Joints
 - Permit movement in two planes (biaxial).
 - Examples: wrist joint.

5. Saddle Joints

- Allow movement similar to condyloid but with greater range; biaxial.
- Examples: carpometacarpal joint of the thumb.

6. Ball-and-Socket Joints

- Multiaxial joints allowing movement in all planes.
- Examples: shoulder, hip.

Functions of Articulations

Joints serve multiple roles, including:

- Mobility: Facilitating a wide range of movements necessary for daily activities and complex actions.
- Stability: Maintaining the integrity of the skeletal framework.
- Support and Weight Bearing: Especially in weight-bearing joints like hips and knees.
- Growth and Development: Growth plates (epiphyseal plates) allow bones to lengthen during development.

Body Movements: Types and Mechanics

Body movements are actions performed by muscles that produce motion at joints. These movements are categorized based on the axes and planes of motion, and understanding them is key to analyzing human activity.

Fundamental Types of Movements

1. Flexion and Extension

- Flexion: Bending a joint, decreasing the angle between bones.
- Extension: Straightening a joint, increasing the angle.
- Example: Bending or straightening the elbow.

2. Abduction and Adduction

- Abduction: Moving a limb away from the midline.
- Adduction: Moving a limb toward the midline.
- Example: Raising arm sideways (abduction), lowering it back (adduction).

3. Rotation

- Turning a bone around its longitudinal axis.
- Example: Turning the head side to side.

4. Circumduction

- A circular movement combining flexion, extension, abduction, and adduction.
- Example: Moving the arm in a circle.

5. Supination and Pronation

- Supination: Rotating the forearm so that the palm faces upward or forward.
- Pronation: Rotating to face downward or backward.

6. Dorsiflexion and Plantar Flexion

- Dorsiflexion: Lifting the foot upwards towards the shin.
- Plantar Flexion: Pointing the toes downward.

7. Inversion and Eversion

- Movements of the sole of the foot inward (inversion) or outward (eversion).

8. Protraction and Retraction

- Moving a part of the body forward (protraction) or backward (retraction).
- Example: Moving the jaw forward or backward.

9. Elevation and Depression

- Moving a part superiorly (elevation) or inferiorly (depression).
- Example: Shrugging shoulders.

Movements Along Specific Axes and Planes

- Sagittal Plane: Divides the body into left and right parts. Movements: flexion and extension.
- Frontal (Coronal) Plane: Divides the body into front and back. Movements: abduction and adduction.
- Transverse (Horizontal) Plane: Divides the body into top and bottom. Movements: rotation, circumduction.

Muscle Actions and their Role in Movements

Muscles are categorized based on their roles in producing movement:

- Agonists (Prime Movers): Muscles chiefly responsible for movement.
- Antagonists: Muscles opposing the prime mover.
- Synergists: Muscles assisting the prime mover.
- Fixators: Muscles stabilizing the origin of the prime mover.

For example, during elbow flexion:

- Biceps brachii: Prime mover (agonist).
- Triceps brachii: Antagonist.
- Brachialis: Synergist.

Joint Stability and Range of Motion

Stability and mobility are often inversely related; some joints are inherently more stable, while others are more flexible.

- Factors Contributing to Stability:
 - Ligament strength and arrangement
 - Muscle tone and contractions
 - Joint capsule integrity
 - Bony congruence
- Range of Motion (ROM):
 - The extent of movement possible at a joint.
 - Influenced by joint structure, ligament laxity, muscle flexibility, and age.

Understanding the balance of stability and mobility is crucial in injury prevention, rehabilitation, and athletic training.

Common Joint Disorders and Movement Limitations

Knowledge of joint function helps in diagnosing and managing disorders such as:

- Arthritis: Inflammation leading to pain and decreased ROM.
- Dislocations: Complete displacement of bones at a joint.
- Sprains: Injury to ligaments, resulting in instability.
- Bursitis: Inflammation of bursae affecting joint movement.

Practical Applications of Articulations and Movements

Understanding joint types and movements is vital for:

- Designing effective physical
