Itx 1040 drive belt: Optimization of an Elastic Drive Belt System Using an Algorithm of Automated Optimal Design Gerald T. Lioy, 1985 In this design project an elastic drive belt system is optimized using an algorithm of automated optional design, AOD. First, some basic background information on AOD and elastic drive belt systems is reviewed. An elastic drive belt system configuration is defined, mathematically formulated, and optimized. The mathematical formulation, including a set of constraints, is completely derived. It is set up to be as general as possible so that it may be applied to a wide variety of different problems. In several places the formulation uses the recommendations of an elastic drive belt manufacturer for a good design. A sample design problem is optimized using the AOD-P519RE algorithm of AOD. The following optimization studies are carried out: 1. Minimization of bearing load. 2. Maximization of power transmission. 3. Minimization of power requirement. Standard belt material compounds and thicknesses are considered. To illustrate the usefulness of algorithms of AOD, an existing hand calculation design method for elastic drive belt systems is demonstrated. These two techniques are then compared as design optimization tools. It is shown that an algorithm of AOD is superior for this purpose. At the conclusion of this project several detailed discussions regarding the work and results are presented. The AOD search process, derivation of the final equation set, significance of the results, and other items are analyzed. A set of final design recommendations for the sample problem are given and a list of conclusions is presented.--Abstract.

largely into the calculations and forms as important a part in the daily operations in the machine-shop as the endless belt for the transmission of power. The lathe, the drill, the planer, the shaping-machine - in short, almost without exception, all machine-tools - are commonly driven from the shop-shaft by means of belts and pulleys; and we can scarcely glance into a shop or factory of any description without encountering a mass of belts which seem at first sight to monopolize every nook in the building and leave little or no room for anything else. Notwithstanding the countless thousands of belts for transmission in use and constantly being replaced in the shops and factories of America; notwithstanding the fact that many thousands of dollars are consumed every year by the rapid wear and destruction of our machine-belts, and the immense field thereby opened for the practical study and application of the principles of economy in this connection - there is no branch of machine-construction which is to-day in as crude and unsatisfactory a state of development as this all-important transmission by belt and pulley.
